

ASSISMENT 5

MALREDDY-192372015

1. Given two sorted arrays `nums1` and `nums2` of size `m` and `n` respectively, return the median of the two sorted arrays. The overall run time complexity should be $O(\log(m+n))$. Example 1: Input: `nums1 = [1,3]`, `nums2 = [2]`

main.py	Output
<pre>1 def findMedianSortedArrays(nums1, nums2): 2 merged = sorted(nums1 + nums2) 3 n = len(merged) 4 if n % 2 == 0: 5 return (merged[n // 2 - 1] + merged[n // 2]) / 2 6 else: 7 return merged[n // 2] 8 9 nums1 = [1, 3] 10 nums2 = [2] 11 result = findMedianSortedArrays(nums1, nums2) 12 print(result) # Output: 2.0</pre>	<pre>2 === Code Execution Successful ===</pre>

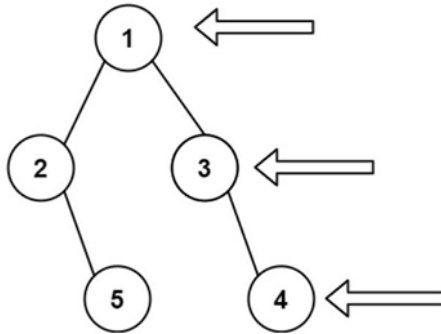

2. Given two integers `dividend` and `divisor`, divide two integers without using multiplication, division, and mod operator. The integer division should truncate toward zero, which means losing its fractional part. For example, 8.345 would be truncated to 8, and -2.7335 would be truncated to -2. Return the quotient after dividing `dividend` by `divisor`. Note: Assume we are dealing with an environment that could only store integers within the 32-bit signed integer range: $[-2^{31}, 2^{31} - 1]$. For this problem, if the quotient is strictly greater than $2^{31} - 1$, then return $2^{31} - 1$, and if the quotient is strictly less than -2^{31} , then return -2^{31}

main.py	Output
<pre>1 def divide(dividend, divisor): 2 if dividend == 0: 3 return 0 4 negative = (dividend < 0) != (divisor < 0) 5 dividend, divisor = abs(dividend), abs(divisor) 6 quotient = 0 7 while dividend >= divisor: 8 dividend -= divisor 9 quotient += 1 10 return -quotient if negative else min(quotient, 2**31 - 1) 11 dividend = 10 12 divisor = 3 13 print(divide(dividend, divisor)) 14</pre>	<pre>3 === Code Execution Successful ===</pre>

3.

3. Given the root of a binary tree, imagine yourself standing on the right side of it, return the values of the nodes you can see ordered from top to bottom.

Example 1:

Input: root = [1, 2, 3, null, 5, null, 4]

Output: [1,3,4]

main.py	Output
<pre>1 class TreeNode: 2 def __init__(self, val=0, left=None, right=None): 3 self.val = val 4 self.left = left 5 self.right = right 6 class Solution: 7 def rightSideView(self, root: TreeNode): 8 if not root: 9 return [] 10 result = [] 11 queue = [root] 12 while queue: 13 level_count = len(queue) 14 for i in range(level_count): 15 node = queue.pop(0) 16 if i == level_count - 1: 17 result.append(node.val) 18 if node.left: 19 queue.append(node.left) 20 if node.right: 21 queue.append(node.right) 22 return result 23 if __name__ == "__main__": 24 root = TreeNode(1) 25 root.left = TreeNode(2) 26 root.right = TreeNode(3) 27 root.left.right = TreeNode(5) 28 root.right.right = TreeNode(4) 29 solution = Solution() 30 right_view = solution.rightSideView(root) 31 print("Right view of the binary tree:", right_view) 32</pre>	<p>Right view of the binary tree: [1, 3, 4]</p> <p>=== Code Execution Successful ===</p>

4. Given an integer array `nums`, move all 0's to the end of it while maintaining the relative order of the non-zero elements. Note that you must do this in-place without making a copy of the array.
Example 1:

Input: `nums = [0,1,0,3,12]` Output: `[1,3,12,0,0]`

main.py	Output
<pre>1 def moveZeros(nums): 2 zero_ptr = 0 3 for i in range(len(nums)): 4 if nums[i] != 0: 5 nums[i], nums[zero_ptr] = nums[zero_ptr], nums[i] 6 zero_ptr += 1 7 return nums 8 nums = [0, 1, 0, 3, 12] 9 result = moveZeros(nums) 10 print(result) 11</pre>	<pre>[1, 3, 12, 0, 0] === Code Execution Successful ===</pre>

5. Given a positive integer `num`, return true if `num` is a perfect square or false otherwise. A perfect square is an integer that is the square of an integer. In other words, it is the product of some integer with itself. You must not use any built-in library function, such as `sqrt`. Example 1: Input: `num = 16`
Output: true

main.py	Output
<pre>1 def isPerfectSquare(num): 2 i = 1 3 while i * i <= num: 4 if i * i == num: 5 return True 6 i += 1 7 return False 8 num = 16 9 print(isPerfectSquare(num)) 10</pre>	<pre>True === Code Execution Successful ===</pre>
